2) Project Title and Description

Running Buddy:

An app that helps runners decide where they should run, and what they should wear for their run. It would then recommend what you should wear (long sleeves, gloves, etc), and would take into account temperature, wind speed, and humidity. The second part is the route recommender, which would have a list of user saved routes with different parameters such as terrain (concrete, asphalt, dirt) and elevation change. A weekly workout planner would also be included, which could provide workout schedules (for certain goals). We also hope to implement shoe mileage tracking.

3) Accomplishments and overall project status during this increment

As this was the final increment, our main goal was to flesh out the backend and deliver a fully developed prototype as the project came to an end. Most of our time was spent adding functionality to the buttons and features that were developed on the frontend during increment two, and making sure that the data that was then created via these functional elements was persistent and could be edited and deleted. Along with this, making sure that the data was accurately reflected and integrated across the entire application was another goal of this increment, as there are multiple pieces that interact with each other in different sections. One example of this is routes, where they are displayed via recommendation on the home page, can be edited, added, and deleted on the routes page, and can be selected by a user for a workout on the add workout page within the calendar. We also began to implement boundary testing to prevent the user from creating faulty data, such as negative numbers where those values would not make sense, and confirming that the algorithms worked properly based on the weather and cold sensitivity slider. Additionally, training plan functionality was fully implemented, allowing users to select a plan type and start date, with progress tracked over time. Workout generation was integrated so that users automatically receive structured daily workouts based on their selected plan. Weather based features were also added, enabling users to select a date and time to view forecasted conditions and receive clothing recommendations within the supported forecast range.

4) Challenges, changes in the plan and scope of the project and things that went wrong during this increment

The main challenge in this increment was making sure that the data that was displayed on each page was the most current version, along with properly binding it across the entire application. In increment two, our frontend was developed, but this increment brought full functionality to those features that we had created. There were some issues with attempting to connect all of the pieces together, where solutions in one section would break another. One such example is the route recommendation engine. This connects both the routes page to the home page, and when it was developed, it created issues loading the home page due to a disconnect in the bindings within the routes section. Furthermore, making sure that the option choices were properly displayed, specifically when it came to selecting a route in the add workouts page, was a bit of a struggle because of the constant need to refresh after every update of data. These problems were easy to fix, however, so this increment for the most part was relatively smooth sailing.

5) Team Member Contribution for this increment

Kirra Orndorff

- a) included details as to how the main goal of this increment was full functionality; discussed that data persistence across the entire application was the main challenge this increment; wrote the stakeholder email
- b) no changes were made to the RD doc this increment
- c) included information regarding connecting the pages together through integration and how the NWS integration was tested
- d) created the routes page, the add route page, the basics of the calendar page, the recommended routes algorithm and the add workout detail page
- e) discussed profile tab and some unimplemented features

Alexander Jubran

- a) implemented the clothing recommender algorithm, connected it to the weather, and some bug fixes
- e) discussed shoe tab in final video

Lauren Chang

- a) Talked to and emailed professor about situation
- e) Presented the calendar tab with the training plan associated. Discussed unimplemented features in association with the calendar.

Riley Galpin

- a) Contributed to fixing bugs including route count, routes display, and weather display on IOS devices.
- b) Contributed to testing and catching bugs by manually going through each screen and trying all functionality including edge cases.
- c) the video

Michael Greenberg

- a) Accomplishment section.
- d) Built workout generation for training plans. Added weather based date selection with clothing suggestions. Implemented plan selection, progress tracking, and home screen workout display.
- e) the video

6) Plans for the next increment

N/A

7) Stakeholder Communication

Dear Stakeholders,

We're excited to announce that Running Buddy's fully functional prototype is complete!

This final phase was focused on bringing all features to life. The weather-based outfit recommender now factors in temperature, wind, humidity, and personal cold sensitivity. Routes flow seamlessly across the app, surfacing as recommendations on the home screen and as options when logging workouts in the calendar. We also added input validation to prevent erroneous data entry, keeping your recommendations accurate and reliable. A major priority this cycle was data consistency. It was important to ensure that any addition, edit, or deletion is immediately reflected everywhere across the app. Running Buddy is now ready for your hands-on feedback. As runners yourselves, your perspective is exactly what we need to take this prototype to the next level.

Warm regards,

The Running Buddy Development Team
